

**SoCalGas-146**

**SoCalGas Annual Review Meeting with the Division of Oil and Gas  
(1990).**

**I.19-06-016**

**ALJs: Hecht/Poirier**

**Date Served: March 17, 2021**

1990

SOUTHERN CALIFORNIA GAS COMPANY  
ALISO CANYON FIELD  
ANNUAL REVIEW MEETING  
with the  
DIVISION OF OIL AND GAS

## TABLE OF CONTENTS

### Geology

- Interpretation
- Studies in progress

### Project Performance

- Report on injection pressures and reservoir pressures
- Volume of gas in storage vs. pressure/z (Hysteresis Curve)
- Reservoir data changes or additions
- Reservoir fluid distribution
- Annual rate of oil produced vs. cumulative oil (former oil reservoirs)
- Cumulative gas vs cumulative oil production
- Changes in the composition of gas injected
- Unusual or unpredictable occurrences

### Conservation (Waste or loss of natural resources)

- Report on monitoring programs
- Losses detected and corrective measures taken
- Changes or additions to monitoring programs

### Pollution Prevention

- Report on well shut-in system (a) status of installation, (b) testing results on critical wells, (c) alterations to system
- Water disposal methods
- Spill prevention and containment

### Operations

- Wells drilled, abandoned, converted, or reworked
- Unusual occurrences or problems

## GEOLOGY

A 1978 geologic study of the Aliso Canyon field performed by the consulting firm Scientific Software Corporation indicated that gas had not migrated out of the defined boundaries (Frew fault on the west, Ward fault on the north and fluid contacts on south and east). The structure maps were revised in 1988 and in 1990 to incorporate 13 new wells that have been drilled over the past 12 years and to include new interpretations of fault locations. Isobaric maps drawn during recent shut-in periods indicate partial permeability barriers in the field with wells on the north west side (IW 70, F-2 and F-3), as well as IW 69 behaving differently than the rest of the field. Reservoir studies conducted during the early 1980's showed that a shift in the P/Z hysteresis curve was caused by gas moving into low permeability areas of the field. Efforts to stop this movement has proved successful by not injecting into the tight areas of the field. Between November 1980 (Point 14) and November 1989 (Point 29) the P/Z curve has shifted to the left by 5 Bcf.

Updated versions of structure maps and field cross-sections were used to determine vertical displacement along the Ward, Frew, and sub-Frew faults. All of these boundary faults are reverse faults which bound the north and west flanks of the storage reservoir. Structure maps indicate the vertical displacement along the Ward fault is 300'-400' in the northwest section of the field. In the northeast section of the field, vertical displacement along the Ward fault is 1000'-1400'. North/south trending cross-sections through the west flank of the reservoir show the vertical displacements along the Frew and sub-Frew faults. The vertical displacement along the Frew fault ranges from 6000'-6500'. The vertical displacement along the sub-Frew fault is estimated at 300'-400'.

New studies in progress for 1990 are being conducted to understand the fluid distribution across the field. In the Upper Sesnon Zone the gas cap has expanded down-dip to all but about 8 of the deepest wells in the southwest part of the field. In the Lower Sesnon Zone the gas-oil contact is only about 400 feet deeper than the original gas-oil contact, and some of the gas withdrawal wells tend to load up at low inventories. The conclusions of the 1978 Geological Study showed:

1. Reservoir Boundaries

South and East Sides:	Water aquifer
West Side:	Frew Fault
North Side:	Ward/Roosa Fault

2. SS-1-0 is an observation well which tests the communication between the storage zone and the Ward fault block. No gas shows were found in the Ward Fault block and subsequent pressure monitoring of the sub-Roosa fault block shows no communication with the storage zone.
3. The geologic structure is sound and competent to hold storage gas within the reservoir boundaries.

4. The northwest area represents 30% of initial gas cap volume, and 12% of the total reservoir pore volume.
5. The shifts to the right and left on the Hysteresis Curve has been due to:
  - a. Gas moving into and out of tighter areas of the reservoir and then returning to the more permeable areas.
  - b. Some fault blocks, with restricted communication, being repressurized and depressurized.
  - c. Gas going into and out of the oil band.
6. Reasons for tilted water/oil contact along the south flank:
  - a. Sand-shale facies change, possible pinchout on the south and east flanks.
  - b. Step segments offset by older faults.

In 1987, while abandoning Porter 4, the MP shale was tested for possible migrated gas from well leaks. The interval produced no gas.

The following table summarizes some of the historical and geologic data for the gas storage reservoir.

TABLE 1. Aliso Canyon Statistical Data

Historical Information

Year storage field was activated	1973
Discovery pressure	3602 psig

Reservoir Characteristics

Name and geologic age of formation	Sesnon - Miocene Frew - Eocene
Formation structure	Faulted anticline
Formation thickness	150' to 400'
Depth range for wells (MD)	7100' to 9400'
Average Bottomhole pressure at 70 Bcf	3600 psig
Average Bottomhole temperature	180°F
Cushion gas	91 Bcf
Working gas	70 Bcf

**Operations**

**Gas Storage Wells** **96**

**Observation Wells** **9**

**RLA:hr**  
**5/30/90**

## PROJECT PERFORMANCE

### Injection Pressures

Figures 1, 2, and 3 show the variation of the average reservoir pressure with inventory for the 1987-1989 injection cycles. The stabilized reservoir pressure is always maintained at less than discovery pressure (3602 psig.)

Assuming a 0.7 psi/ft. fracture gradient for an 8000 ft. well, the wellbore pressure required to fracture the formation will be 5600 psig, which is 2000 psig greater than we ever encounter at Aliso Canyon.

### Hysteresis Curve

Figure 4 is an updated graph of P/Z versus inventory (the data is also listed in Table 2). The shift in reservoir pressures from 1974 to date when plotted versus injected gas content is a combination of the repressurization of low permeability gas cap areas and of gas going into solution in crude oil some distance from the wellbore.

During the past four years the reservoir has not been filled to capacity. As a result the hysteresis curve has shifted to the left. This could be a result of gas coming out of solution or gas coming from tight regions of the reservoir. We have seen no evidence of pressure changes in observation wells penetrating the Ward fault block. We have no observation wells in the sub-Frew block, but with the displacement of 300-400 feet, it is unlikely that any gas moved there. The volumetric weighting of reservoir blocks is used to calculate the current hysteresis curve, Figures 4 and 5.

### Fluid Distributions

Figures 6 and 7 show structure maps for the S-4 and S-8 zone tops, respectively. Also shown are the original and best interpretation of current gas/oil and oil/water contacts. There is essentially no oil belt on the east flank which results in a gas/water contact along that flank. Very little changes in fluid contacts have been observed.

### Reservoir Data Changes or Additions

No new wells have been drilled since the last DOG review. Most reservoir parameters are fairly well fixed from our major geologic study and log analysis. Subtle changes in gas saturation may have caused significant changes in the effective gas permeability and individual well deliverabilities. Each well is tested two to three times per year to determine its optimum sand free deliverability.

Project Performance  
Page 2

Oil Production

Table 3 presents annual oil production figures, starting from 1970 to date. From discovery the cumulative oil production through 1989 was 25,722,878 barrels. Figure 8 shows the annual oil production versus cumulative oil production.

Figure 9 is a graph of cumulative gas production versus cumulative oil production.

The performance of the reservoir since 1970 is shown on Figure 10. The plots of annual pressures decline through 1972. The semiannual plot from the start of storage operations illustrates the high and low range of inventory pressures. The estimated recoverable reserves for Aliso Canyon as of 12/31/89 is 770,000 Bbls. A 10% annual decline rate is used for Aliso Canyon oil production estimates.

Gas Analysis

Source gas for Aliso Canyon storage is still predominantly from the Permian Basin Mid-Continent area. As received, both the hydrocarbon distribution and helium content of this gas distinguish it from California gas. Table 4 represents a typical storage gas analysis.

Unusual Occurrences

There have been no unusual occurrences since the May 1989 DOG review.

## CONSERVATION

### Monitoring Programs

A monitoring program is developed as a means of ensuring the integrity of the gas storage operation of the reservoir. The variety of the programs include integrity logs on all storage zone and observation wells, pressure monitoring of selected observation wells around and above the storage zone, gas analysis monitoring of abandoned wells located in and around the storage project and the monitoring of production of nearby fields (Figures 14-21). As a whole, the monitoring programs provides a focused means of assuring a safe and efficient operation.

Table 5 lists the normal monitoring activities at this field. The well problems listed in Table 6 were discovered, analyzed, and remedied using routine operating procedures. Examples of field data that are effective monitoring tools are as follows:

OPERATIONS

May 1989 through May 1990

1.	New wells drilled:	None	
2.	Well workovers:	<u>Well</u>	<u>Reason</u>
		FF 35B (IW82)	Regravel pack
		FF 35C (IW67)	Repair casing leak; regravel pack
		F 2	Plugback lower zone
		MA 1A	Regravel pack
		MA 5A	Inspect casing; replace sliding sleeve
		P 32C (IW78)	Inspect casing; regravel pack; install protective string
		P 34	Regravel pack
3.	Well converted to observation:	None	
4.	Wells abandoned:	<u>Well</u>	<u>Reason</u>
		FF 31	Ineffective observation well
		FF 35	Ineffective observation well
		P 42	Ineffective storage well, hazardous location
		PF 1	High risk location, landslide area, ineffective storage well
		PF 2	Same as PF 1

No unusual incidents or problems have occurred since the last  
DOG review meeting.

LDK:hr  
5/24/90

## ENVIRONMENTAL PROTECTION

### WELL SAFETY SYSTEMS

All wells at Aliso Canyon are equipped with surface safety systems that are designed to shut the well in to prevent loss of gas and oil in the event of damage to surface piping. The surface safety system consists of fail-close pneumatic operated gate valves that are closed by any of the following:

1. Low pressure pilot - shuts well in if a break in the piping causes pressure to drop below 300 psi.
2. High pressure pilot - shuts well in if pressure in withdrawal line exceeds 710 psi.
3. Sacrificial sand erosion probe - shuts well in if sand erosion wears hole in thin walled probe.
4. Fusible plug - shuts well in if a fire occurs in well cellar.
5. Remote shutdown station - allows well to be shut in manually from no closer than 150 feet away from wellhead.

All surface safety systems are tested twice a year.

Aliso Canyon does not have any critical wells that would require subsurface safety valves. However, three wells that are in high risk landslide areas are equipped with subsurface safety valves that are actuated by the same system as the surface safety valve. These valves are tested twice a year.

All workover and drilling rigs at Aliso Canyon are equipped with Class III or better blowout prevention equipment.

### WATER DISPOSAL

Produced water is disposed of by Texaco. Texaco blends produced water from their wells in the Porter, Aliso and Del Aliso Zones with water from Southern California Gas Company wells in the Sesnon-Frew and re-injects it into the Porter and Aliso Zones.

### SPILL PREVENTION

The Company has various written procedures that deal with spills of hazardous liquids. These procedures attempt to prevent such spills by requiring periodic inspections of wellheads, piping and tankage. The procedures also contain plans for dealing with spills if they occur. All tanks have secondary containment walls. All natural water courses within the field have catch basins that will trap any oil that would reach them if a field gathering line developed a leak. The oil could then be removed by vacuum truck.
